## Chapter 07: Consistency & Replication

Version: February 21, 2011

### Contents

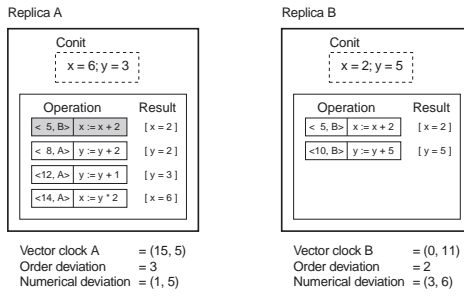

Chapter
01: Introduction
02: Architectures
03: Processes
04: Communication
05: Naming
06: Synchronization
07: Consistency & Replication
08: Fault Tolerance
09: Security
10: Distributed Object-Based Systems
11: Distributed File Systems
12: Distributed Web-Based Systems
13: Distributed Coordination-Based Systems

### Consistency & replication

- Introduction (what's it all about)
- Data-centric consistency
- Client-centric consistency
- Replica management
- Consistency protocols

### Example: Conit

- Conit (contains the variables  $x$  and  $y$ )**
- Each replica maintains a **vector clock**
  - $B$  sends  $A$  operation  $\langle 5, B \rangle: x := x + 2$ ;  $A$  has made this operation **permanent** (cannot be rolled back)

### Example: Conit

- Conit (contains the variables  $x$  and  $y$ )**
- $A$  has three **pending** operations  $\Rightarrow$  order deviation = 3
  - $A$  has missed **one** operation from  $B$ , yielding a max diff of 5 units  $\Rightarrow$  (1, 5)

### Sequential consistency

#### Definition

The result of any execution is the same as if the operations of all processes were executed in some sequential order, and the operations of each individual process appear in this sequence in the order specified by its program.

## Server-initiated replicas

- Keep track of access counts per file, aggregated by considering server closest to requesting clients
- Number of accesses drops below threshold  $D \Rightarrow$  drop file
- Number of accesses exceeds threshold  $R \Rightarrow$  replicate file
- Number of access between  $D$  and  $R \Rightarrow$  migrate file

## Content distribution

### Model

Consider only a client-server combination:

- Propagate only notification/invalidation of update (often used for caches)
- Transfer data from one copy to another (distributed databases)
- Propagate the update *operation* to other copies (also called active replication)

### Note

No single approach is the best, but depends highly on available bandwidth and read-to-write ratio at replicas.

## Content distribution

- Pushing updates: server-initiated approach, in which update is propagated regardless whether target asked for it.
- Pulling updates: client-initiated approach, in which client requests to be updated.

Issue	Push-based	Pull-based
1:	List of client caches	None
2:	Update (and possibly fetch update)	Poll and update
3:	Immediate (or fetch-update time)	Fetch-update time
1: State at server 2: Messages to be exchanged 3: Response time at the client		

## Continuous consistency: Numerical errors

**Principal operation**

Consider a data item  $x$  and let  $weight(W)$  denote the numerical change in its value after a write operation  $W$ . Assume that  $\forall W : weight(W) > 0$ .

$W$  is initially forwarded to one of the  $N$  replicas, denoted as  $origin(W)$ .  $TW[i, j]$  are the writes executed by server  $S_i$  that originated from  $S_j$ :

$$TW[i, j] = \sum \{ weight(W) \mid origin(W) = S_j \ \& \ W \in \log(S_i) \}$$

## Continuous consistency: Numerical errors

**Note**

Actual value  $v(t)$  of  $x$ :

$$v(t) = v_{init} + \sum_{k=1}^N TW[k, k]$$

value  $v_i$  of  $x$  at replica  $i$ :

$$v_i = v_{init} + \sum_{k=1}^N TW[i, k]$$

35 / 42

35 / 42

## Continuous consistency: Numerical errors

**Problem**

We need to ensure that  $v(t) - v_i < \delta_i$  for every server  $S_i$ .

**Approach**

Let every server  $S_k$  maintain a **view**  $TW_k[i, j]$  of what it believes is the value of  $TW[i, j]$ . This information can be **gossiped** when an update is propagated.

**Note**

$$0 \leq TW_k[i, j] \leq TW[i, j] \leq TW[j, j]$$
